

AD/BR7208/SSI

Governance of business-to-business data in the European Union

IRU POSITION

- Data and the digitalisation of the road transport sector has the potential to bring benefits to companies, consumers and society.
- Currently, transport operators, which are large data generators, find it difficult to know or understand how companies receiving the data they generate handle their business/non-personal data. Data aggregators typically decide who can access data, and how it can be used and re-used.
- This lack of transparency, combined with the absence of a binding legal framework recognising the rights of business data generators, makes transport operators hesitant to share the data they generate.
- Some 80% of the over 900,000 transport operators carrying goods and passengers in the EU are small and medium sized enterprises (SMEs), with between one and 10 vehicles. Upgrading to digital tools and the necessary staff training require significant investment. Cost is a major consideration for small operators that should be taken into account when developing a data governance framework.

Commercial road transport operators call on regulators to adopt the following measures on B2B data sharing and ensure there is a harmonised EU approach:

- 1. Sharing of business-generated data should always be voluntary. If partners do decide to share their data, they should be able to rely upon a binding legal framework, which will promote trust among business partners.
- 2. Recognise the rights of data generators to access the data produced by aggregators on the basis of their raw input, as well as in connection with the use and re-use of such data by third parties.
- 3. Any data governance model should take into account the costs of the data economy for data generators. Financial support and incentives for SMEs are needed to enable them to make the transition.

ANALYSIS

Transport operators do not currently know or understand how companies handle the data generated by their businesses. Data aggregators, which may collect data with or without express consent, typically decide who has access to the data and how to use and re-use it, often even without the knowledge or consent, of the initial data generators. If the practices of data aggregators are not regulated effectively, it may lead to inefficiencies in digital markets, disrupting competition for both data generators and data aggregators.

Steps must be taken to ensure equal opportunities for all business partners in the digital ecosystem. **IRU calls on policy makers to adopt a binding EU legal framework for the provision of B2B data** based on the main pillars outlined below. The B2B data framework must cover any type of data flowing between businesses, irrespective of how it is generated, including data created by transport operators and/or data automatically generated by a machine or vehicle owned by a transport operator. The principles below should also apply in the context of business-to-government data flows, where authorities further open the data or otherwise share it with for-profit organisations.

- i. The voluntary provision of data as the guiding principle. Forcing the provision of business data by making it mandatory would stifle innovation and could hamper the competitiveness of businesses, while further increasing the power of a few actors at the expense of the SMEs and start-ups. B2B data exchange should continue to rely on voluntary contractual agreements, in which provisions regarding the treatment of data should be clearly and explicitly stated.
- ii. **Responsible actors**. The obligations and liability of data aggregators should be clearly defined and the rights of the data generators should be explicitly recognised, including:
 - a. Access (reciprocity): business data generators' access to the data they generate, whether in raw or processed format, should be guaranteed. It is essential to preserve data security when data is being exchanged. Access controls throughout data value chains, in adherence to strict security standards, will be key to foster data sharing among different actors across data ecosystems.
 - b. **Overview:** business data generators should have the right to receive a data processing transparency report, detailing, inter alia, how the data they generated are stored and for how long, and how they are used and transferred to third parties.
 - c. **Consent:** the explicit consent of business data generators should be ensured for the collection of data generated by their business, for the storage, use (including further processing and aggregation) and re-use of such data over time. The language used in legal agreements to take the consent of data generators should be clear, simple and precise. The aspects of data processing should be transparent to boost trust and mitigate concerns about data misappropriation.
 - d. **Portability:** data generators, including transport operators, must have the right to take their data stored in one platform and transfer them to other providers. Data lock-in systems must not be allowed as they foster monopolies.
 - e. **Compensation:** the future framework on data must also ensure that data generators are able to ask for and receive financial remuneration in exchange for the data provided. Moreover, a mechanism should be put in place for data generators to seek compensation for damages if their rights are breached, especially when such a breach occurs intentionally and/or due to the negligence of a party that did not perform its duties diligently.
- iii. **Financial support for SMEs**: the costs for the industry of transitioning to a digital economy should not be underestimated. Operators will have to develop their digital infrastructure, such as software for data exchange, enabling interoperability with

other operators and digital service providers, such as e-CMR, for goods transport and Mobility as a Service vendors for passenger transport services. In addition, support for technology innovation should be underpinned by a strong focus on skills. Workers need to be upskilled, particularly in the transport sector, to take full advantage of the opportunities offered by data-based business models in critical areas such as artificial intelligence (AI), machine learning (ML) or cloud computing. In addition, to meet the challenges of the digital economy, the transport sector needs data experts. Information campaigns on general data literacy in the workforce should be implemented at national and European level.

iv. Standardisation and interoperability: an absence of uniform standards, for example APIs/data formats, makes interoperability between platforms difficult. It increases the risk of lock-in, with one platform for data generators, as the cost of investing in software that can respond to the diverse data format requirements of various platforms is discouraging for businesses. In the transport sector, transport operators need simple, uniform and accessible APIs/data formats.

Data has become an asset to companies¹ and in the transport sector the trend to collect, store, share and use/re-use the data generated, especially by businesses, will continue at an increasing pace with the development of the internet of things (IoT), machine learning (ML), artificial intelligence (AI) and automation.² Innovative solutions, such as connected vehicles, smart cities and digital platforms will lead to an increase in data generation.

The same players in the mobility space can have different roles in different circumstances. For example, a company can act as a data generator when an aggregator in the upstream of the data value chain collects the data it generates. The same company can act as a data aggregator if, in the course of its business, it also collects data of other companies in the downstream of the data chain. For the purpose of this position paper and of further data regulation, the notion of data generator and data aggregator must be assessed on a case-by-case basis, depending on the respective role of the company and its relevant position in the data value chain. For example, companies acting as fleet managers or transport service providers aggregate data from individual vehicles or operators but can be considered data generator vis-àvis a third party which is in the upstream of the data value chain.

The European Commission, through its <u>Strategy for Data</u>, has shared its vision to create a single European data market to drive competitiveness in the global data economy. So far, the emphasis has been on the protection of personal data (individuals).

In the context of sharing non-personal (business) data, a number of challenges need to be tackled, such as:

- i. **B2B data governance**. The lack of clarity on data generators' access to data stored and/or further processed by data aggregators on the basis of their raw input, as well as in connection with the use and re-use of such data by third parties.
- ii. **Transparency and trust.** The lack of trust by transport operators that the data they generate will be used in line with or even without contractual agreements, given the often unequal bargaining power between the parties and the lack of transparency.

¹ Estimates suggest that the world will generate about <u>90 zettabytes</u> (approximately a billion terabytes) of data in 2020. By 2025, worldwide data is expected to grow to <u>175 zettabytes</u>, with much of the data residing in the cloud.

² It is estimated that the global AI-derived business value in 2020 is likely to be about USD 2.65 trillion. Between 2018 and 2019, the percentage of organisations using AI technologies increased from 4% to 14%.

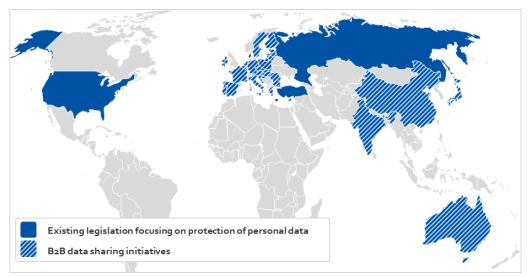

- iii. **Financial**. The lack of economic incentives, including the fear of losing a competitive edge and/or the fear of no economic return, together with the lack of clarity on total cost for data generators to develop data driven systems.
- iv. **Data misappropriation**. The risk of misappropriation of the data (as single or aggregate data) by third parties.

The current legal framework does not support B2B data sharing practices

EU laws provide general rules, which could be applied to data handling from different perspectives, as well as sectoral legislation with a focus on specific types of data flow.³ The scope of intervention through general EU rules, such as competition law, is limited and procedures are excessively lengthy. Regarding specific legislation on data, a concrete recognition of the rights of data generators only exists in the context of business to consumer data flow (i.e. personal data).

In other jurisdictions, such as Australia, China, India, Japan and the United States of America, the existing legislation is also insufficient to protect the interests of the parties involved when it comes to sharing of non-personal data. In some places, legislative efforts are being considered to establish appropriate data sharing mechanisms (see diagram below).

In the EU and worldwide, the legal framework governing B2B data sharing is nonexistent or too vague and the position of data generators, including transport operators, is not adequately taken into account.

Online platforms and competition

Data is a major economic asset,⁴ since the use of data underpins the business models of all online platforms. The massive increase in collection, processing and storage capacities has increased concerns about the concentration of information. Online platforms bring enormous benefits and the COVID-19 crisis has made their advantages even more apparent. However, a small number of large online platforms⁵ are in a position that allow them to act as gatekeepers, with adverse effects for innovation and competition. This could lead to:

³ See IRU overview of the existing governance framework for data.

⁴ For example, the total value of European consumers' personal data in 2011 was estimated at EUR 315 billion. In 2020, big data in the European Union should become a market worth USD 1,000 billion (Report by Boston Consulting Group).

⁵ In a list of the worlds' 70 largest online platforms with respect to <u>market capitalisation</u> – America has 73%, China has 18% and Europe has 4% of the platforms (Economist, 2020).

- i. Data generators being in an asymmetric/unequal bargaining position vis-à-vis online platforms. The online platform might act as a private regulator, which limits data generators' ability to make decisions freely and efficiently.
- ii. Data generators not having access to the data necessary to compete, and access to data produced on the basis of their raw input and managed by a single online platform is often cumbersome. Innovative start-ups and SMEs might face hurdles to enter the market or compete on merit, ultimately leading to a few players dominating.

For example, in the case of Mobility as a Service (MaaS), ⁶ as with many other digital markets, once stabilised, these markets may naturally shift to favour one provider. Loss of customer control by the transport operator, which is a characteristic of this type of intermediation market, will amplify the dependence on MaaS vendors, especially if combined with data lock-in imposed by some vendors. To address this challenge, a legal framework on data governance should confer to transport operators rights such as data reciprocity and portability (the possibility for a platform user to retrieve its data and/or move it to other platforms).
